

From developer to defender

If you know **Python**, you're already ahead

Python is the **#1 language in cyber.** You already know it

Scripting & Automation

Automate recon, scanning, and reporting. Most security tooling is Python-first.

Exploit Development

Write PoCs, fuzz targets, and custom payloads all in Python.

Malware Analysis

Parse, decompile, and reverse engineer scripts. Fluency is everything.

Beyond Python

Other **languages** that translate directly into cyber

C / C++

Memory exploits, kernel-level vulns, reverse engineering binaries.

JavaScript

XSS, DOM injection, client-side attack surface analysis.

Bash / Shell

Living-off-the-land attacks, log parsing, incident response.

Go / Rust

Modern malware, C2 tooling, and high-performance security tools.

The real advantage

Cyber isn't a new language, it's a **new context**

**You already think in
logic and systems.**

Security is just applying that
to the other side.

**Most security tools
are open source.**

You've been reading, modifying and
extending them from day one.

**The best security
engineers write code.**

That's not a bonus skill, it's the
baseline expectation.

Your **next step**

**YOUR DEV SKILLS ARE
THE FOUNDATION.**

Now build on them.

Make the switch
